Textbook

- Scheduling – Theory, Algorithms, and Systems
  Michael Pinedo
  2nd edition, 2002
  Prentice-Hall Inc.
  Pearson Education

- The lecture is based on this textbook.

- These slides are an extract from this book. They are to be used only for this lecture and as a complement to the book.
Scheduling Problem

Constraints

Tasks
(Job(s))

Objective(s)

Areas:
- Manufacturing and production
- Transportations and distribution
- Information - processing

Time
Resources
(Machines)
Example 1: Paper Bag Factory

- different types of paper bags
- 3 production stages
  - printing of the logo
  - gluing of the side
  - sewing of one or both ends
- several machines for each stage
  - differences in speed and function
  - processing speed and processing quantity
  - setup time for a change of the bag type
- due time and late penalty
- minimization of late penalties, setup times
Example 2
Gate Assignments at Airport

- different types of planes (size)
- different types of gates (size, location)
- flight schedule
  - randomness (weather, take off policy)
- service time at gate
  - deplaning of passengers
  - service of airplane
  - boarding of passengers
- minimization of work for airline personnel
- minimization of airplane delay
Example 3  Tasks in a CPU

- different applications
  - unknown processing time
  - known distributions (average, variance)
  - priority level

- multitasking environment
  - preemption

- minimization of the sum of expected weighted completion times
Information Flow Diagram in a Manufacturing System

- Production planning, master scheduling
  - Orders, demand forecasts
  - Capacities, due dates
- Material requirements, planning, capacity planning
  - Material requirements
- Scheduling and rescheduling
  - Shop orders, release dates
  - Detailed scheduling
  - Schedule
- Dispatching
- Shopfloor management
  - Shop status
  - Data collection
  - Job loading
  - Shopfloor
Information Flow Diagram in a Service System

Database → Forecasting

Scheduling

Data → Prices rules

Accept/ reject (conditions) → Place order, make reservations

Customer

Status (history) → Forecasts

Forecasting

Yield management
\( p_{ij} \): processing time of job j on machine i

\( p_j \): identical processing time of job j on all machines

\( r_i \): release data of job j (earliest starting time)

\( d_j \): due date of job j (completion of job j after \( d_j \) results in a late penalty)

\( d_j \): deadline (\( d_j \) must be met)
Machine Environment (1)

$\mathbf{I}$: single machine

$\mathbf{P}_m$: $m$ identical machines in parallel

$\mathbf{Q}_m$: $m$ machines in parallel with different speeds

$\mathbf{R}_m$: $m$ unrelated machines in parallel

$\mathbf{F}_m$: flow shop with $m$ machines in series
  - each job must be processed on each machine using the same route.
  - queues between the machines
    FIFO queues, see also permutation flow shop

$\mathbf{F}_c$: flexible flow shop with $c$ stages in series and several identical machines at each stage,
one job needs processing on only one (arbitrary) machine at each stage.
Machine Environment (2)

\( J_m \) : job shop with \( m \) machines with a separate predetermined route for each job.
A machine may be visited more than once by a job.
This is called \textit{recirculation}.

\( FJ_c \) : flexible job shop with \( c \) stages and several identical machines at each stage, see FF\(_c\).

\( O_m \) : Open shop with \( m \) machines
  - Each job must be processed on each machine.
Restrictions and Constraints (1)

- **release dates**, see also job properties
- **sequence dependent setup times**
  - $S_{ijk}$: setup time between job $j$ and job $k$ on machine $i$
  - (S_{jk}: identical setup times for all machines)
  - (S_{0j}: startup for job $j$)
  - (S_{j0}: cleanup for job $j$)
- **preemption (prmp)**
  - The processing of a job can be interrupted and later resumed (on the same or another machine).
- **precedence constraints (prec)**
  - Certain jobs must be completed before another job can be started.
    - representation as a directed acyclic graph (DAG)
Restrictions and Constraints (2)

- **machine breakdowns (brkdwn)**
  - machines are not continuously available: For instance, $m(t)$ identical parallel machines are available at time $t$.

- **machine eligibility restrictions ($M_j$)**
  - $M_j$ denotes the set of parallel machines that can process job $j$ (for $P_m$ and $Q_m$).

- **permutation (prmu), see $F_m$**

- **blocking (block)**
  - A completed job cannot move from one machine to the next due to limited buffer space in the queue. Therefore, it blocks the previous machine ($F_m$, $FF_c$).
Restrictions and Constraints (3)

- no – wait (nwt)
  - A job is not allowed to wait between two successive executions on different machines ($F_m, FF_c$).

- recirculation (recirc)
Objective Functions (1)

- Completion time of job $j$: $C_j$

- Lateness of job $j$: $L_j = C_j - d_j$
  - The lateness may be positive or negative.

- Tardiness: $T_j = \max (L_j, 0)$

- Number of late jobs: $U_j = \begin{cases} 1 & \text{if } C_j > d_j, \\ 0 & \text{otherwise} \end{cases}$
Objective Functions (2)

- **Makespan**: $C_{\text{max}} = \max (C_1, \ldots, C_n)$
  - Completion time of the last job in the system

- **Maximum lateness**: $L_{\text{max}} = \max (L_1, \ldots, L_n)$
Objective Functions (3)

- Total weighted completion time: $\Sigma w_j C_j$
- Total weighted flow time: $(\Sigma w_j (C_j - r_j)) = \Sigma w_j C_j - \Sigma w_j r_j$
- Discounted total weighted completion time:
  $\Rightarrow (\Sigma w_j (1 - e^{-rC_j})) \quad 0<r<1$
- Total weighted tardiness: $\Sigma w_j T_j$
- Weighted number of tardy jobs: $\Sigma w_j U_j$
- Regular objective functions:
  $\Rightarrow$ non decreasing in $C_1, ..., C_n$
  $\Rightarrow$ Earliness: $E_j = \max (-L_j, 0)$
    - non increasing in $C_j$
  $\Sigma E_j + \Sigma T_j, \Sigma w_j E_j + \Sigma w_j T_j \Rightarrow$ not regular obj. functions
Description of a Scheduling Problem

\[ \alpha \mid \beta \mid \gamma \]

- Machine environment
- Objective (to be minimized)
- Constraints, processing, characteristics

Examples:
- Paper bag factory: FF3 | r_j | \( \Sigma w_j T_j \)
- Gate assignment: P_m | r_j, M_j | \( \Sigma w_j T_j \)
- Tasks in a CPU: l | r_j prmp | \( \Sigma w_j C_j \)
- Traveling Salesman: l | s_{jk} | C_{max}
Classes of Schedules

- **Nondelay (greedy) schedule**
  - No machine is kept idle while a task is waiting for processing.
  
  An optimal schedule need not be nondelay!

Example: P2 | prec | $C_{\text{max}}$

<table>

= job completed
Active Schedule

It is not possible to construct another schedule by changing the order of processing on the machines and having at least one task finishing earlier without any task finishing later.

There is at least one optimal and active schedule for \( J_m || \gamma \) if the objective function is regular.

Example:
Consider a job shop with three machines and two jobs.
- **Job 1** needs 1 time unit on machine 1 and 3 time units on machine 2.
- **Job 2** needs 2 time units on machine 3 and 3 time units on machine 2.
- **Both jobs** have to be processed last on machine 2.
Example of an Active Schedule

It is clear that this schedule is active as reversing the sequence of the two jobs on machine 2 postpones the processing of job 2. However, the schedule is neither nondelay nor optimal. Machine 2 remains idle until time 2 while there is a job available for processing at time 1.
Semi – active Schedule

No task can be completed earlier without changing the order of processing on any one of the machines.

Example:
Consider again a schedule with three machines and two jobs. The routing of the two jobs is the same as in the previous example.

- The processing times of job 1 on machines 1 and 2 are both equal to 1.
- The processing times of job 2 on machines 2 and 3 are both equal to 2.
Example of a Semi – active Schedule

Consider the schedule under which job 2 is processed on machine 2 before job 1. This implies that job 2 starts its processing on machine 2 at time 2 and job 1 starts its processing on machine 2 at time 4. This schedule is semi-active. However, it is not active as job 1 can be processed on machine 2 without delaying the processing of job 2 on machine 2.
A Venn diagram of the three classes of nonpreemptive schedules; the nondelay schedules, the active schedules, and the semi-active schedules.
Complexity Preliminaries

- \( T(n) = O(f(n)) \) if \( T(n) < c \cdot f(n) \) holds for some \( c > 0 \) and all \( n > n_0 \).

- Example \( 1500 + 100n^2 + 5n^3 = O(n^3) \)

- Input size of a simple scheduling problem
  \[ n \cdot \log_2(\text{max } p_j) \]
  - number of jobs
  - maximal processing time
  - In binary encoding
Mergesort

$n$ input values at most $n \cdot \log_2 n$ comparison steps

time complexity of mergesort: $O(n \cdot \log n)$
Some problems are special cases of other problems:

Notation: $\alpha_1 | \beta_1 | \gamma_1 \propto$ (reduces to) $\alpha_2 | \beta_2 | \gamma_2$

Examples:

$1 || \sum C_j \propto 1 || \sum w_j C_j \propto P_m || \sum w_j C_j \propto Q_m | \text{prec} | \sum w_j C_j$

Complex reduction cases:

$\alpha | \beta | L_{\text{max}} \propto \alpha | \beta | \sum U_j$

$\alpha | \beta | L_{\text{max}} \propto \alpha | \beta | \sum T_j$

Variation of $d_j$ and logarithmic search
Processing Restrictions and Constraints

\[ r_j \quad S_{jk} \quad prmp \quad prec \quad brkdw \quad M_j \quad block \quad nwt \quad recrc \]

\[ 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \]
Objective Functions

\[
\sum w_j T_j \quad \sum w_j U_j \\
\sum w_j C_j \\
\Sigma C_j \\
\Sigma T_j \\
L_{\text{max}} \\
C_{\text{max}}
\]
Time Complexity of Algorithms

- Easy (polynomial time complexity): There is an algorithm that optimally solves the problem with time complexity $O((n \cdot \log(\max p_j))^k)$ for some fixed $k$.

- NP-hard in the ordinary sense (pseudo polynomial time complexity): The problem cannot be optimally solved by an algorithm with polynomial time complexity but with an algorithm of time complexity $O((n \cdot \max p_j)^k)$.

- NP-hard in the strong sense: The problem cannot be optimally solved by an algorithm with pseudo polynomial complexity.
Problem Classification

Deterministic scheduling problems

- polynomial time solution
- NP – hard
  - NP-hard ordinary sense
  - strongly NP-hard
  - pseudo polynomial solution
Partition

Given positive integers $a_1, \ldots, a_t$ and $b = \frac{1}{2} \sum_{j=1}^{t} a_j$, do there exist two disjoint subsets $S_1$ and $S_2$ such that

$$\sum_{j \in S_i} a_j = b$$

for $i=1,2$?

Partition is NP-hard in the ordinary sense.
3-Partition

Given positive integers $a_1,\ldots, a_{3t}, b$ with

$$\frac{b}{4} < a_j < \frac{b}{2}, \quad j = 1,\ldots, 3t,$$

and

$$\sum_{j=1}^{3t} a_j = tb$$

do there exist $t$ pairwise disjoint three element subsets $S_i \subset \{1,\ldots, 3t\}$ such that

$$\sum_{j \in S_i} a_j = b \quad \text{for } i=1,\ldots, t?$$

3-Partition is strongly NP-hard.
Proof of NP-Hardness

A scheduling problem is NP-hard in the ordinary sense if
- partition (or a similar problem) can be reduced to this problem with a polynomial time algorithm and
- there is an algorithm with pseudo polynomial time complexity that solves the scheduling problem.

A scheduling problem is strongly NP-hard if
- 3-partition (or a similar problem) can be reduced to this problem with a polynomial time algorithm.
Complexity of Makespan Problems

- **Hard**
  - $FF_c \parallel C_{max}$
  - $P2 \parallel C_{max}$
  - $1 \parallel C_{max}$

- **Easy**
  - $J_m \parallel C_{max}$
  - $F2 \parallel C_{max}$
Complexity of Maximum Lateness Problems

- $P_m \parallel L_{\text{max}}$
- $1 \mid r_j \mid L_{\text{max}}$
- $1 \mid r_j, \text{prmp} \mid L_{\text{max}}$
- $1 \mid \text{prmp} \mid L_{\text{max}}$

Hard

Easy
Total Weighted Completion Time (1)

1 || Σ w_j C_j : Schedule the jobs in Smith order \( \frac{w_j}{p_j} \).

The Weighted Shortest Processing Time first (WSPT) rule is optimal for 1 || Σ w_j C_j.

Proof by contradiction and localization:

*If the WSPT rule is violated then it is violated by a pair of neighboring task h and k.*

\[
\begin{array}{c|c|c}
  t & h & k \\
\end{array}
\]

S_1: Σ w_j C_j = ... + w_h(t+p_h) + w_k(t + p_h + p_k)
Total Weighted Completion Time (2)

\[ S_2: \sum w_j C_j = \ldots + w_k(t+p_k) + w_h(t + p_k + p_h) \]

Difference between both schedules \( S_1 \) und \( S_2 \):

\[ w_k p_h - w_h p_k > 0 \quad \text{(improvement by exchange)} \]

\[ \frac{w_k}{p_k} > \frac{w_h}{p_h} \]

The complexity is dominated by sorting \( \Rightarrow O(n \log(n)) \)
Use of precedence constraints: $1|\text{prec}|\sum w_j C_j$

Only independent chains are allowed at first!

Chain of jobs $1, \ldots, k$

$l^*$ satisfies

$$\frac{\sum_{j=1}^{l^*} w_j}{\sum_{j=1}^{l^*} p_j} = \max_{1 \leq l \leq k} \left( \frac{\sum_{j=1}^{l} w_j}{\sum_{j=1}^{l} p_j} \right)$$

$l^*$ determines the $\delta$-factor of the chain $1, \ldots, k$
 Whenever the machine is available, select among the remaining chains the one with the highest $\delta$-factor. Schedule all jobs from this chain without interruption until the job that determines the $\delta$-factor.

**Proof concept**

There is an optimal schedule that processes all jobs $1, \ldots, l^*$ in succession + Pairwise interchange of chains
Consider the following two chains:

1 → 2 → 3 → 4

and

5 → 6 → 7

The weights and processing times of the jobs are given in the following table.

<table>
<thead>
<tr>
<th>jobs</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
</tr>
</thead>
<tbody>
<tr>
<td>w_j</td>
<td>6</td>
<td>18</td>
<td>12</td>
<td>8</td>
<td>8</td>
<td>17</td>
<td>18</td>
</tr>
<tr>
<td>p_j</td>
<td>3</td>
<td>6</td>
<td>6</td>
<td>5</td>
<td>4</td>
<td>8</td>
<td>10</td>
</tr>
</tbody>
</table>
Example: Total Weighted Completion Time with Chains (2)

- δ-factor of first chain \(\frac{6+18}{3+6} = \frac{24}{9} \rightarrow \) Job 2
- δ-factor of second chain \(\frac{8+17}{4+8} = \frac{25}{12} < \frac{24}{9} \rightarrow \) Job 6
  - Jobs 1 and 2 are scheduled first.
- δ-factor of remaining part of first chain \(\frac{12}{6} < \frac{25}{12} \rightarrow \) Job 3
  - Jobs 5 and 6 are scheduled next.

\[
\frac{w_7}{p_7} = \frac{18}{10} < \frac{12}{6} \rightarrow \text{Job 3 is scheduled next.}
\]

\[
\frac{w_4}{p_4} = \frac{8}{5} < \frac{18}{10} \rightarrow \text{Job 7 is scheduled next and finally job 4}
\]
Other Total Completion Time Problems

1 | prec | $\sum w_j C_j$ is strongly NP hard for arbitrary precedence constraints.

1 | $r_j , prmp$ | $\sum w_j C_j$ is strongly NP hard.

- The WSPT (remaining processing time) rule is not optimal.
  - Example: Select another job that can be completed before the release date of the next job.

1 | $r_j , prmp$ | $\sum C_j$ is easy.

1 | $r_j$ | $\sum C_j$ is strongly NP hard.

1 || $\sum w_j (1 - e^{-rC_j})$ can be solved optimally with the Weighted Discounted Shortest Processing Time first (WDSPT) rule:

$$\frac{w_j \cdot e^{-rp_j}}{1 - e^{-rp_j}}$$
Maximum Cost

- **General problem:** $1 \mid \text{prec} \mid h_{\text{max}}$
  - $h_j(t)$: nondecreasing cost function
  - $h_{\text{max}} = \max (h_1(C_1), \ldots, h_n(C_n))$

- **Backward dynamic programming algorithm**
  - Makespan $C_{\text{max}} = \sum p_j$
  - $J$: set of all jobs already scheduled (backwards) in
    \[
    [C_{\text{max}} - \sum_{j \in J} p_j, C_{\text{max}}]
    \]
  - $J^c = \{1, \ldots, n\} \setminus J$: set of jobs still to be scheduled
  - $J' \subseteq J^c$: set jobs that can be scheduled under consideration of precedence constraints.
Algorithm: Minimizing Maximum Cost

- **Step 1** Set $J = \emptyset$, let $J^c = \{1, \ldots, n\}$ and $J'$ be the set of all jobs with no successors.

- **Step 2** Let $j^* \in J'$ be such that

  $$h_{j^*}\left(\sum_{j \in J^c} p_j\right) = \min_{j \in J'} h_j\left(\sum_{k \in J^c} p_k\right)$$

  Add $j^*$ to $J$.
  Delete $j^*$ from $J^c$.
  Modify $J'$ to represent the new set of schedulable jobs.

- **Step 3** If $J^c = \emptyset$ then STOP otherwise go to Step 2.

This algorithm yields an optimal schedule for $1 \mid prec \mid h_{\text{max}}$. 
Minimizing Maximum Cost: Proof of Optimality (1)

- Assumption: The optimal schedule $S_{\text{opt}}$ and the schedule $S$ of the previous algorithm are identical at positions $k+1, \ldots, n$.
- At position $k$ with completion time $t$, there is job $j^{**}$ in $S_{\text{opt}}$ and job $j^*$ with $h_{j^{**}}(t) \geq h_{j^*}(t)$ in $S$.
  - Job $j^*$ is at position $k' < k$ in $S_{\text{opt}}$.
- Create schedule $S'$ by removing job $j^*$ in $S_{\text{opt}}$ and putting it at position $k$.
  - $h_j(C_j)$ does not increase for all jobs $\{1, \ldots, n\} \setminus \{j^*\}$.
  - $h_{j^*}(t) \leq h_{j^{**}}(t) \leq h_{\text{max}}(S_{\text{opt}})$ holds due to the algorithm.
- Therefore, schedule $S'$ is optimal as $h_{\text{max}}(S') \leq h_{\text{max}}(S_{\text{opt}})$ holds.
  - An optimal schedule and schedule $S$ are identical at positions $k, k+1, \ldots, n$. 
Minimizing Maximum Cost: Proof of Optimality (2)
Minimizing Maximum Cost: Example

<table>
<thead>
<tr>
<th>jobs</th>
<th>1</th>
<th>2</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>$p_j$</td>
<td>2</td>
<td>3</td>
<td>5</td>
</tr>
<tr>
<td>$h_j(C_j)$</td>
<td>$1 + C_j$</td>
<td>$1.2 C_j$</td>
<td>10</td>
</tr>
</tbody>
</table>

- $C_{max} = 2+3+5 = 10$

- $h_3(10) = 10 < h_1(10) = 11 < h_2(10) = 12$
  - Job 3 is scheduled last.

- $h_2(10 - p_3) = h_2(5) = 6 = h_1(5)$
  - Optimal schedules 1,2,3 and 2,1,3
Maximum Lateness (1)

- 1 || L_{max} is a special case of 1 | prec | h_{max}.
  \[ h_j = C_j - d_j \rightarrow \text{Earliest Due Date first} \]

- 1 | r_j | L_{max} is strongly NP complete.

**Proof:**
Reduction of 3-Partition to 1 | r_j | L_{max}

Integers \( a_1, \ldots, a_{3t}, b \)

\[ \frac{b}{4} < a_j < \frac{b}{2} \]

\[ \sum_{j=1}^{3t} a_j = t \cdot b \]

\[ r_j = j \cdot b + (j - 1), \quad p_j = 1, \quad d_j = j \cdot b + j, \quad \forall j = 1, \ldots, t - 1 \]

\[ r_j = 0, \quad p_j = a_{j-t+1}, \quad d_j = t \cdot b + (t - 1), \quad \forall j = t, \ldots, 4t - 1 \]
Maximum Lateness (2)

$L_{\text{max}} = 0$ if every job $j \in \{1, ..., t - 1\}$ can be processed from $r_j$ to $r_j + p_j = d_j$ and all other jobs can be partitioned over $t$ intervals of length $b$.

$\Rightarrow 3$ – Partition has a solution.

$1 \mid r_j \mid L_{\text{max}}$ is strongly NP – hard.
Optimal Solution for $1 \mid r_j \mid L_{\text{max}} (1)$

Optimal solution for $1 \mid r_j \mid L_{\text{max}}$: Branch and bound method

- Tree with $n+1$ levels
  - Level 0: 1 root node
  - Level 1: $n$ nodes:
    A specific job scheduled at the first position of the schedule.
  - Level 2: $n \cdot (n-1)$ nodes:
    from each node of level 1 there are $n – 1$ edges to nodes of level 2:
    a second specific job scheduled at the second position of the schedule.

- $n!/k!$ nodes at level $k$:
  each node specifies the first $k$ positions of the schedule.
Optimal Solution for 1 | r_j | L_{max} (2)

Assumption: \[ r_{jk} \geq \min_{l \in J} (\max(t, r_l) + p_l) \]

J: jobs that are not scheduled at the father node of level k – 1

\( t \): makespan at the father node of level k – 1

Job \( j_k \) need not be considered at a node of level k with this specific father at level k – 1.

Finding bounds:

If there is a better schedule than the one generated by a branch then the branch can be ignored.

1 | r_j, prmp | L_{max} can be solved by the preemptive Earliest Due Date (EDD) first rule.

→ This produces a nondelay schedule.

→ The resulting schedule is optimal if it is nonpreemptive.
Branch and Bound Applied to Minimizing Maximum Lateness (1)

<table>
<thead>
<tr>
<th>jobs</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
</tr>
</thead>
<tbody>
<tr>
<td>$p_j$</td>
<td>4</td>
<td>2</td>
<td>6</td>
<td>5</td>
</tr>
<tr>
<td>$r_j$</td>
<td>0</td>
<td>1</td>
<td>3</td>
<td>5</td>
</tr>
<tr>

<td>12</td>
<td>11</td>
<td>10</td>
</tr>
</tbody>
</table>

- Level 1 (1, ?, ?, ?) (2, ?, ?, ?) (3, ?, ?, ?) (4, ?, ?, ?)
  - Disregard (3, ?, ?, ?) and (4, ?, ?, ?) as job 2 can be completed at $r_3$ and $r_4$ at the latest.
- Lower bound for node (1, ?, ?,?):

```
| 0 | 1 | 3 | 4 | 10 | 3 | 2 | 17 |
```

$L_{\text{max}} = 5$

- Lower bound for node (2, ?, ?,?):

```
| 0 | 1 | 3 | 1 | 7 | 4 | 12 | 3 | 18 |
```

$L_{\text{max}} = 7$
Lower bound for node (1, 2, ?, ?):
- 1, 2, 3, 4 (nonpreemptive, $L_{\text{max}} = 6$)
- Disregard (2, ?, ?, ?).

Lower bound for node (1, 3, ?, ?):
- 1, 3, 4, 2 (nonpreemptive, $L_{\text{max}} = 5$)
- Disregard (1, 2, ?, ?).

Lower bound for node (1, 4, ?, ?):
- 1, 4, 3, 2 (nonpreemptive, $L_{\text{max}} = 6$)

A similar approach can be used for $1 \mid r_j, \text{prec} \mid L_{\text{max}}$.
- The additional precedence constraints may lead to less nodes in the branch and bound tree.
Number of Tardy Jobs: 1 \| \Sigma U_j

- The jobs are partitioned into 2 sets.
  - set A: all jobs that meet their due dates
    - These jobs are scheduled according to the EDD rule.
  - set B: all jobs that do not meet their due dates
    - These jobs are not scheduled!

- The problem is solved with a forward algorithm.
  - J: Jobs that are already scheduled
  - J^d: Jobs that have been considered and are assigned to set B
  - J^c: Jobs that are not yet considered
Algorithm for Solving $1 \parallel \sum U_j$

- **Step 1**
  Set $J = \emptyset$, $J^d = \emptyset$, and $J^c = \{1, \ldots, n\}$.

- **Step 2**
  Let $j^*$ denote the job that satisfies $d_{j^*} = \min_{j \in J^c} (d_j)$.
  Add $j^*$ to $J$.
  Delete $j^*$ from $J^c$.
  Go to Step 3.

- **Step 3**
  If $\sum_{j \in J} p_j \leq d_{j^*}$ then go to Step 4,
  otherwise
  let $k^*$ denote the job which satisfies $p_{k^*} = \max_{j \in J} (p_j)$.
  Delete $k^*$ from $J$.
  Add $k^*$ to $J^d$.

- **Step 4**
  If $J^c = \emptyset$ then STOP, otherwise go to Step 2.
The computational complexity is determined by sorting $O(n \cdot \log(n))$.

We assume that all jobs are ordered by their due dates.

$\Rightarrow \quad d_1 \leq d_2 \leq \ldots \leq d_n$

$J_k$ is a subset of jobs $\{1, \ldots, k\}$ such that

(I) it has the maximum number $N_k$ of jobs in $\{1, \ldots, k\}$ completed by their due dates,

(II) of all sets with $N_k$ jobs in $\{1, \ldots, k\}$ completed by their due dates $J_k$ is the set with the smallest total processing time.

$\Rightarrow \quad J_n$ corresponds to an optimal schedule.
Proof by induction

The claim is correct for k=1.

We assume that it is correct for an arbitrary k.

1. Job k+1 is added to set J_k and it is completed by its due date.
   ⇒ J_{k+1} = J_k \cup \{k+1\} and |J_{k+1}| = N_k+1 = N_{k+1}.

2. Job k+1 is added to set J_k and it is not completed on time.
   ⇒ The job with the longest processing time is deleted.
   ⇒ N_{k+1} = N_k
   ⇒ The total processing time of J_k is not increased.
   ⇒ No other subset of \{1, \ldots, k+1\} can have N_k on-time completions and a smaller processing time.
1 || \( \Sigma U_j \): Example

Total Tardiness (1)

1 || Σ T_j: NP hard in the ordinary sense.

⇒ There is a pseudo polynomial time algorithm to solve the problem.

Properties of the solution:

1. If p_j ≤ p_k and d_j ≤ d_k holds then there exists an optimal sequence in which job j is scheduled before job k.

⇒ This is an Elimination criterion or Dominance result.
   A large number of sequences can be disregarded. ⇒
   New precedence constraints are introduced. ⇒
   The problem becomes easier.
2 problem instances with processing times $p_1, \ldots, p_n$

First instance: $d_1, \ldots, d_n$

$$C'_k: \text{latest possible completion time of job } k \text{ in an optimal sequence (S')}$$

Second instance:

$$d_1, \ldots, d_{k-1}, \max\{d_k, C'_k\}, d_{k+1}, \ldots, d_n$$

$S'': \text{an optimal sequence}$

$C_j'': \text{completion time of job } j \text{ in sequence } S''$

2. Any sequence that is optimal for the second instance is optimal for the first instance as well.
Assumption: \(d_1 \leq \ldots \leq d_n\) and \(p_k = \max (p_1, \ldots, p_n)\)

\(\Rightarrow\) \(k\)th smallest due date has the largest processing time.

3. There is an integer \(\delta, 0 \leq \delta \leq n-k\) such that there is an optimal sequence \(S\) in which job \(k\) is preceded by all other jobs \(j\) with \(j \leq k+\delta\) and followed by all jobs \(j\) with \(j \geq k+\delta\).

\(\Rightarrow\) An optimal sequence consists of
1. jobs 1, ..., \(k-1\), \(k+1\), ..., \(k+\delta\) in some order
2. job \(k\)
3. jobs \(k+\delta+1\), ..., \(n\) in some order

The completion time of job \(k\) is given by \(C_k(\delta) = \sum_{j \leq k+\delta} p_j\).
Minimizing Total Tardiness (1)

- J(j, l, k): all jobs in the set \{j, ..., l\} with a processing time \leq p_k but job k is not in J(j, l, k).

- V(J(j, l, k), t) is the total tardiness of J(j, l, k) in an optimal sequence that starts at time t.

**Algorithm: Minimizing Total Tardiness**

Initial conditions: 
\[
V(\emptyset, t) = 0 \\
V(\{j\}, t) = \max(0, t + p_j - d_j)
\]

Recursive relation: 
\[
V(J(j, l, k), t) = \min_{\delta} \left( V(J(j, k' + \delta, k'), t) + \max(0, C_{k'}(\delta) - d_{k'}) + V(J(k' + \delta + 1, l, k'), C_{k'}(\delta)) \right)
\]

where \( k' \) is such that 
\[
p_{k'} = \max( p_{j'} | j' \in J(j, l, k) )
\]

Optimal value function 
\[
V(\{1, ..., n\}, 0)
\]
Minimizing Total Tardiness (2)

- At most $O(n^3)$ subsets $J(j, l, k)$ and $\Sigma p_j$ points in $t$
  - $O(n^3 \cdot \Sigma p_j)$ recursive equations

- Each recursion takes $O(n)$ time
  - Running time $O(n^4 \cdot \Sigma p_j)$

Algorithm PTAS Minimizing Total Tardiness
Minimizing Total Tardiness
Example (1)

- \( k=3 \) (largest processing time) \( \Rightarrow 0 \leq \delta \leq 2 = 5 - 3 \)

- \( V(\{1, 2, \ldots, 5\}, 0) = \text{min} \left\{ \begin{array}{l}
V(\{1, 3, 3\}, 0) + 81 + V(\{4, 5, 3\}, 347) \\
V(\{1, 4, 3\}, 0) + 164 + V(\{5, 5, 3\}, 430) \\
V(\{1, 5, 3\}, 0) + 294 + V(\emptyset, 560)
\end{array} \right\} \)

- \( V(\{1, 3, 3\}, 0) = 0 \) for sequences 1, 2 and 2, 1

- \( V(\{4, 5, 3\}, 347) = 347 + 83 - 336 + 347 + 83 + 130 - 337 = 317 \) for sequence 4, 5
Minimizing Total Tardiness
Example (2)

- $V(J(1, 4, 3), 0) = 0$ for sequences 1, 2, 4 and 2, 1, 4

- $V(J(5, 5, 3), 430) = 430 + 130 - 337 = 223$

- $V(J(1, 5, 3), 0) = 76$ for sequences 1, 2, 4, 5 and 2, 1, 4, 5

\[ V(\{1, ..., 5\}, 0) = \min \left\{ \begin{array}{l} 0 + 81 + 317 \\ 0 + 164 + 223 \\ 76 + 294 + 0 \end{array} \right\} = 370 \]

1, 2, 4, 5, 3 and 2, 1, 4, 5, 3 are optimal sequences.
Total Weighted Tardiness

1 || Σ w_j T_j is strongly NP complete.
   → Proof by reduction of 3 – Partition

Dominance result
If there are two jobs j and k with d_j ≤ d_k, p_j ≤ p_k and w_j ≥ w_k then there is an optimal sequence in which job j appears before job k.

The Minimizing Total Tardiness algorithm can solve this problem if w_j ≤ w_k holds for all jobs j and k with p_j ≥ p_k.
Total Tardiness
An Approximation Scheme (1)

For NP-hard problems, it is frequently interesting to find in polynomial time a (approximate) solution that is close to optimal.

Fully Polynomial Time Approximation Scheme A for $1 \parallel \sum T_j$:

$$\sum T_j(A) \leq (1 + \varepsilon) \sum T_j(OPT)$$

The running time is bounded by a polynomial (fixed degree) in $n$ and $1/\varepsilon$. 
a) n jobs can be scheduled with 0 total tardiness iff (if and only if) the EDD schedule has 0 total tardiness.

\[ T_{\text{max}}(\text{EDD}) \leq \sum T_j(OPT) \leq \sum T_j(EDD) \leq n \cdot T_{\text{max}}(EDD) \]

maximum tardiness of any job in the EDD schedule
b) \( V(J, t) \): Minimum total tardiness of job subset \( J \) assuming processing starts at \( t \).

- There is a time \( t^* \) such that
  \[
  V(J, t) = 0 \quad \text{for} \quad t \leq t^* \quad \text{and} \\
  V(J, t) > 0 \quad \text{for} \quad t > t^*
  \]
  \[\Rightarrow V(J, t^* + \delta) \geq \delta \quad \text{for} \quad \delta \geq 0 \]

- The pseudo polynomial algorithm is used to compute \( V(J, t) \) for
  \[
  \max \{0, t^*\} \leq t \leq n \cdot T_{\text{max}}(EDD)
  \]

- Running time bound \( O(n^5 \cdot T_{\text{max}}(EDD)) \)
Total Tardiness
An Approximation Scheme (4)

c) Rescale $p'_j = \left\lfloor \frac{p_j}{K} \right\rfloor$ and $d'_j = \frac{d_j}{K}$ with some factor $K$.

$S$ is the optimal sequence for rescaled problem.

$\sum T_j^*(S)$ is the total tardiness of sequence $S$ for processing times $K \cdot p'_j \leq p_j$ and due dates $d_j$.

$\sum T_j(S)$ is the total tardiness of sequence $S$ for $p_j < K \cdot (p'_j + 1)$ and $d_j$.

$\sum T_j^*(S) \leq \sum T_j(OPT) \leq \sum T_j(S) < \sum T_j^*(S) + K \cdot \frac{n(n+1)}{2}$

$\sum T_j(S) - \sum T_j(OPT) < K \cdot \frac{n(n+1)}{2}$

Select $K = \frac{2\varepsilon}{n(n+1)} \cdot T_{\text{max}}(\text{EDD})$

$\sum T_j(S) - \sum T_j(OPT) \leq \varepsilon \cdot T_{\text{max}}(\text{EDD})$
Algorithm: PTAS Minimizing Total Tardiness

- **Step 1** Apply EDD and determine $T_{\text{max}}$.
  If $T_{\text{max}} = 0$, then $\sum T_j = 0$ and EDD is optimal; STOP.
  Otherwise set
  $$K = \left( \frac{2\epsilon}{n(n+1)} \right) T_{\text{max}} (\text{EDD})$$

- **Step 2** Rescale processing times and due dates as follows:
  $$p_j' = \left\lfloor \frac{p_j}{K} \right\rfloor$$
  $$d_j' = \frac{d_j}{K}$$

- **Step 3** Apply Algorithm Minimizing Total Tardiness to the rescaled data.

Running time complexity: $O(n^5 \cdot T_{\text{max}}(\text{EDD})/K) = O(n^7/\epsilon)$
PTAS Minimizing Total Tardiness Example

- Optimal sequence 1,2,4,5,3 with total tardiness 3700.
  - Verified by dynamic programming

- $T_{\text{max}}(\text{EDD}) = 2230$
  - If $\epsilon$ is chosen 0.02 then we have $K = 2.973$. 

- Optimal sequences for the rescaled problem: 1,2,4,5,3 and 2,1,4,5,3.
  - Sequence 2,1,4,5,3 has total tardiness 3704 for the original data set.
  - $\sum T_j(2,1,4,5,3) \leq 1.02 \cdot \sum T_j(1,2,4,5,3)$
Objective $\Sigma E_j + \Sigma T_j$

- This problem is harder than total tardiness.
- A special case is considered with $d_j = d$ for all jobs $j$.

Properties of the special case
- No idleness between any two jobs in the optimal schedule
  - The first job does not need to start at time 0.
- Schedule $S$ is divided into 2 disjoint sets

early completion
$C_j \leq d$
job set $J_1$

late completion
$C_j > d$
job set $J_2$
Optimal Schedule:
Early jobs ($J_1$) use *Longest Processing Time first* (LPT)
Late jobs ($J_2$) use *Shortest Processing Time first* (SPT)

There is an optimal schedule such that one job completes exactly at time $d$.

**Proof:** Job $j^*$ starts before and completes after $d$.

If $|J_1| \leq |J_2|$ then
shift schedule to the left until $j^*$ completes at $d$.

If $|J_1| > |J_2|$ then
shift schedule to the right until $j^*$ starts at $d$. 
Minimizing Total Earliness and Tardiness with a Loose Due Date

- Assume that the first job can start its processing after $t = 0$ and $p_1 \geq p_2 \geq ... \geq p_n$ holds.

- **Step 1** Assign job 1 to set $J_1$.
  Set $k = 2$.

- **Step 2** Assign job $k$ to set $J_1$ and job $k + 1$ to set $J_2$ or vice versa.

- **Step 3** If $k + 2 \leq n - 1$, set $k = k + 2$ and go to Step 2.
  If $k + 2 = n$, assign job $n$ to either set $J_1$ or set $J_2$ and STOP.
  If $k + 2 = n + 1$, all jobs have been assigned; STOP.
Minimizing Total Earliness and Tardiness with a Tight Due Date (1)

The problem becomes NP-hard if job processing must start at time 0 and the schedule is nondelay. It is assumed that \( p_1 \geq p_2 \geq \ldots \geq p_n \) holds.

- **Step 1** Set \( \tau_1 = d \) and \( \tau_2 = \sum p_j - d \). Set \( k = 1 \).

- **Step 2** If \( \tau_1 \geq \tau_2 \), assign job \( k \) to the first unfilled position in the sequence and set \( \tau_1 = \tau_1 - p_k \).
  If \( \tau_1 < \tau_2 \), assign job \( k \) to the last unfilled position in the sequence and set \( \tau_2 = \tau_2 - p_k \).

- **Step 3** If \( k < n \), set \( k = k + 1 \) and go to Step 2.
  If \( k = n \), STOP.
6 jobs with $d = 180$

Minimizing Total Earliness and Tardiness with a Tight Due Date (2)
Minimizing Total Earliness and Tardiness (1)

- Objective $\sum w' E_j + \sum w'' T_j$ with $d_j = d$.
  - All previous properties and algorithms for $\sum E_j + \sum T_j$ can be generalized using the difference of $w'$ and $w''$.

- Objective $\sum w_j' E_j + \sum w_j'' T_j$ with $d_j = d$.
  - The LPT/SPT sequence is not necessarily optimal in this case.
  - WLPT and WSPT are used instead.
    - The first part of the sequence is ordered in increasing order of $w_j / p_j$.
    - The second part of the sequence is ordered in decreasing order of $w_j / p_j$. 
Minimizing Total Earliness and Tardiness (2)

- Objective $\sum w_i E_j + \sum w_j T_j$ with different due dates
  - The problem is NP – hard.
  a) Sequence of the jobs
  b) Idle times between the jobs
     - dependent optimization problems
- Objective $\sum w_i E_j + \sum w_j T_j$ with different due dates
  - The problem is NP – hard in the strong sense.
     - It is more difficult than total weighted tardiness.

If a predetermined sequence is given then the timing can be determined in polynomial time.
A scheduling problem is usually solved with respect to the primary objective. If there are several optimal solutions, the best of those solutions is selected according to the secondary objective.

\[ \alpha \mid \beta \mid \gamma_1 \text{ (opt)}, \gamma_2 \]

- SPT/EDD rule

- We consider the problem \( 1 || \sum C_j \text{ (opt)}, L_{\text{max}} \).
  - All jobs are scheduled according to SPT.
  - If several jobs have the same processing time EDD is used to order these jobs.

- SPT/EDD rule
We consider the problem with reversed priorities:

\[ 1 \parallel L_{\text{max}} \text{ (opt), } \Sigma C_j \]

- \( L_{\text{max}} \) is determined with EDD.
- \( z := L_{\text{max}} \)

Transformation of this problem:

\[ \overline{d_j} = d_j + z \]

new deadline    old due dates
Reversal of Priorities (2)

- After the transformation, both problems are equivalent.
  - The optimal schedule minimizes $\Sigma C_j$ and guarantees that each job completes by its deadline.
  - In such a schedule, job $k$ is scheduled last iff
    \[ \overline{d_k} \geq \sum_{j=1}^{n} p_j \quad \text{and} \]
    \[ p_k \geq p_l \quad \text{for all } l \text{ such that } \overline{d_l} \geq \sum_{j=1}^{n} p_j \text{ hold.} \]

- **Proof:** If the first condition is not met, the schedule will miss a deadline.
  - A pairwise exchange of job $l$ and job $k$ (not necessarily adjacent) decreases $\Sigma C_j$ if the second condition is not valid for $l$ and $k$. 
Minimizing Total Completion Time with Deadlines (1)

- **Step 1** Set \( k = n \), \( \tau = \sum_{j=1}^{n} p_j \), \( J^c = \{1, \ldots, n\} \)
- **Step 2** Find \( k^* \) in \( J^c \) such that
  \[ \bar{d}_{k^*} \geq \tau \]
  and
  \[ p_{k^*} \geq p_i \]
  for all jobs \( i \) in \( J^c \) such that
  \[ \bar{d}_i \geq \tau \].
- **Step 3** Decrease \( k \) by 1.
  Decrease \( \tau \) by \( p_{k^*} \).
  Delete job \( k^* \) from \( J^c \).
- **Step 4** If \( k \geq 1 \) go to Step 2, otherwise STOP.

The optimal schedule is always nonpreemptive even if preemptions are allowed.
Minimizing Total Completion Time with Deadlines (2)

<table>
<thead>
<tr>
<th>jobs</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
</tr>
</thead>
<tbody>
<tr>
<td>$p_j$</td>
<td>4</td>
<td>6</td>
<td>2</td>
<td>4</td>
<td>2</td>
</tr>
<tr>
<td>$d_j$</td>
<td>10</td>
<td>12</td>
<td>14</td>
<td>18</td>
<td>18</td>
</tr>
</tbody>
</table>

$\tau = 18 \Rightarrow d_4 = d_5 = 18 \geq \tau$

$p_4 = 4 > 2 = p_5$

→ Last job : 4

$\tau = 18 - p_4 = 14 \Rightarrow d_3 = 14 \geq 14 \quad d_5 = 18 \geq 14$

$p_5 = 2 = p_3$

→ Either job can go in the now last position : 3

$\tau = 14 - p_3 = 12 \Rightarrow d_5 = 18 \geq 12 \quad d_2 = 12 \geq 12$

$p_2 = 6 > 2 = p_5$

→ Next last job: 2

$\tau = 12 - p_2 = 6 \Rightarrow d_5 = 18 \geq 6 \quad d_1 = 10 \geq 12$

$p_1 = 4 > 2 = p_5$

→ Sequence: 5 1 2 3 4
Multiple Objectives

In a generalized approach, multiple objectives are combined in a linear fashion instead of using a priority ordering.

- Objectives: $\gamma_1, \gamma_2$

- Problem with a weighted sum of two (or more) objectives:

  
  \[
  1 \mid \beta \mid \Theta_1 \gamma_1 + \Theta_2 \gamma_2
  \]

- The weights are normalized: $\Theta_1 + \Theta_2 = 1$
A schedule is called pareto-optimal if it is not possible to decrease the value of one objective without increasing the value of the other.

\[ \Theta_1 \rightarrow 0 \quad \text{and} \quad \Theta_2 \rightarrow 1 \]

\[ \Rightarrow 1|\beta|\Theta_1\gamma_1 + \Theta_2\gamma_2 \rightarrow 1|\beta|\gamma_2(\text{opt}), \gamma_1 \]

\[ \Theta_1 \rightarrow 1 \quad \text{and} \quad \Theta_2 \rightarrow 0 \]

\[ \Rightarrow 1|\beta|\Theta_1\gamma_1 + \Theta_2\gamma_2 \rightarrow 1|\beta|\gamma_1(\text{opt}), \gamma_2 \]
Pareto-Optimal Schedule (2)

\[ \gamma_1 : \sum C_j \]

\[ \gamma_2 : L_{\max} \]

\[ L_{\max}(\text{EDD}) \]

\[ L_{\max}(\text{SPT/EDD}) \]
Generation of all pareto-optimal solutions

Find a new pareto-optimal solution:

\[
\begin{align*}
\text{Determine the optimal schedule for } L_{\text{max}}. \\
\text{Determine the minimum increment of } L_{\text{max}} \text{ to decrease the minimum } \sum C_j. \\
\end{align*}
\]

Similar to the minimization of the total weighted completion time with deadlines

Start with the EDD schedule, end with the SPT/EDD schedule.
Pareto-Optimal Solutions (2)

- **Step 1**
  Set \( r = 1 \)
  Set \( L_{\text{max}} = L_{\text{max}}(\text{EDD}) \) and \( \bar{d}_j = d_j + L_{\text{max}} \).

- **Step 2**
  Set \( k = n \) and \( J^c = \{1, \ldots, n\} \).
  Set \( \tau = \sum_{j=1}^{n} p_j \) and \( \delta = \tau \).

- **Step 3**
  Find \( j^* \) in \( J^c \) such that
  \( \bar{d}_{j^*} \geq \tau \), and
  \( p_{j^*} \geq p_l \) for all jobs in \( J^c \) such that \( \bar{d}_l \geq \tau \).
  Put job \( j^* \) in position \( k \) of the sequence.

- **Step 4**
  If there is no job \( l \) such that \( \bar{d}_l < \tau \) and \( p_l > p_{j^*} \), go to Step 5.
  Otherwise find \( j^{**} \) such that
  \[ \tau - \bar{d}_{j^{**}} = \min_{l} (\tau - \bar{d}_l) \]
  for all \( l \) such that \( \bar{d}_l < \tau \) and \( p_l > p_{j^*} \).
  Set \( \delta^{**} = \tau - d_{j^{**}} \).
  If \( \delta^{**} < \delta \), then \( \delta = \delta^{**} \).
Pareto-Optimal Solutions (3)

- **Step 5**
  Decrease $k$ by $l$.
  Decrease $\tau$ by $p_{j^*}$.
  Delete job $j^*$ from $J_c$.
  If $k \geq 1$ go to Step 3, otherwise go to Step 6.

- **Step 6**
  Set $L_{\text{max}} = L_{\text{max}} + \delta$.
  If $L_{\text{max}} > L_{\text{max}}(\text{SPT/EDD})$, then STOP.
  Otherwise set $r = r + 1$, $\bar{d}_j = \bar{d}_j + \delta$, and go to Step 2.

Maximum number of pareto – optimal points

$\Rightarrow n(n - 1)/2 = O(n^2)$

Complexity to determine one pareto – optimal schedule

$\Rightarrow O(n \cdot \log(n))$

$\Rightarrow$ Total complexity $O(n^3 \cdot \log(n))$
Pareto-Optimal Solutions (4)

- \(1 || \Theta_1 \sum w_j C_j + \Theta_2 L_{\text{max}}\)
- Extreme points (WSPT/EDD and EDD) can be determined in polynomial time.
  - The problem with arbitrary weights \(\Theta_1\) and \(\Theta_2\) is NP – hard.
Parallel Machine Models

- A scheduling problem for parallel machines consists of 2 steps:
  - Allocation of jobs to machines
  - Generating a sequence of the jobs on a machine
- A minimal makespan represents a balanced load on the machines.
- Preemption may improve a schedule even if all jobs are released at the same time.
- Most optimal schedules for parallel machines are nondelay.
  - Exception: $R_m \parallel \sum C_j$
- General assumption for all problems: $p_1 \geq p_2 \geq \ldots \geq p_n$
\( P_m \parallel C_{\text{max}} \)

The problem is NP-hard.

\( P_2 \parallel C_{\text{max}} \) is equivalent to Partition.

Heuristic algorithm: Longest processing time first (LPT) rule
Whenever a machine is free, the longest job among those not yet processed is put on this machine.

\( \Rightarrow \) Upper bound:
\[
\frac{C_{\text{max}}(LPT)}{C_{\text{max}}(OPT)} \leq \frac{4}{3} - \frac{1}{3m}
\]

\( \Rightarrow \) The optimal schedule \( C_{\text{max}}(OPT) \) is not necessarily known but the following bound holds:
\[
C_{\text{max}}(OPT) \geq \frac{1}{m} \sum_{j=1}^{n} p_j
\]
Proof of the Bound (1)

- If the claim is not true, then there is a counterexample with the smallest number $n$ of jobs.

- The shortest job $n$ in this counterexample is the last job to start processing (LPT) and the last job to finish processing.
  - If $n$ is not the last job to finish processing, then deletion of $n$ does not change $C_{\text{max}}(LPT)$ while $C_{\text{max}}(OPT)$ cannot increase.
  - A counter example with $n - 1$ jobs

- Under LPT, job $n$ starts at time $C_{\text{max}}(LPT) - p_n$.
  - In time interval $[0, C_{\text{max}}(LPT) - p_n]$, all machines are busy.

\[
C_{\text{max}}(LPT) - p_n \leq \frac{1}{m} \sum_{j=1}^{n-1} p_j
\]
Proof of the Bound (2)

\[ C_{\text{max}}(LPT) \leq p_n + \frac{1}{m} \sum_{j=1}^{n-1} p_j = p_n \left(1 - \frac{1}{m}\right) + \frac{1}{m} \sum_{j=1}^{n} p_j \]

\[ \frac{4}{3} - \frac{1}{3m} < \frac{C_{\text{max}}(LPT)}{C_{\text{max}}(OPT)} \leq \frac{p_n (1 - 1/m)}{C_{\text{max}}(OPT)} + \frac{\sum_{j=1}^{n} p_j / m}{C_{\text{max}}(OPT)} \leq \frac{p_n (1 - 1/m)}{C_{\text{max}}(OPT)} + 1 \]

\[ C_{\text{max}}(OPT) < 3p_n \]

At most two jobs are scheduled on each machine.
For such a problem, LPT is optimal.
A Worst Case Example for LPT

- 4 parallel machines
- \( C_{\text{max}}(\text{OPT}) = 12 = 7 + 5 = 6 + 6 = 4 + 4 + 4 \)
- \( C_{\text{max}}(\text{LPT}) = 15 = (4/3 -1/(3\cdot4))\cdot12 \)

Other Makespan Results

- Arbitrary nondelay schedule \( \frac{C_{\text{max}} \text{(LIST)}}{C_{\text{max}} \text{(OPT)}} \leq 2 - \frac{1}{m} \)

- \( p_m \mid \text{prec} \mid C_{\text{max}} \) with \( 2 \leq m < \infty \) is strongly NP hard even for chains.

- Special case \( m \geq n \): \( p_{\infty} \mid \text{prec} \mid C_{\text{max}} \)
  a) Start all jobs without predecessor at time 0.
  b) Whenever a job finishes, immediately start all its successors for which all predecessors have been completed.

  ➔ Critical Path Method (CPM)
  ➔ Project Evaluation and Review Technique (PERT)
Heuristics Algorithms

- **Critical Path (CP) rule**
  - The job at the head of the longest string of jobs in the precedence constraints graph has the highest priority.
  - $P_m | p_j = 1, \text{tree} | C_{\text{max}}$ is solvable with the CP rule.

- **Largest Number of Successors first (LNS)**
  - The job with the largest total number of successors in the precedence constraints graph has the highest priority.
  - For intrees and chains, LNS is identical to the CP rule.
  - LNS is also optimal for $P_m | p_j = 1, \text{outtree} | C_{\text{max}}$.

- **Generalization for problems with arbitrary processing times**
  - Use of the total amount of processing remaining to be done on the jobs in question.
\[ P_m | p_j = 1, \text{ tree} \mid C_{\text{max}} \]

Number of nodes at the \( r \) highest levels:

\[
H(l_{\text{max}} + 1 - r) = \sum_{k=1}^{r} N(l_{\text{max}} + 1 - k)
\]

Highest level \( l_{\text{max}} \)

\( N(l) \) number of jobs at level \( l \)

Level

for two machines

almost fully connected bipartite graph
LNS for $P_2|p_j=1,\text{prec}|C_{\text{max}}$
A job can only be processed on subset $M_j$ of the $m$ parallel machines.

Here, the sets $M_j$ are nested.

- Exactly 1 of 4 conditions is valid for jobs $j$ and $k$.
  - $M_j$ is equal to $M_k$ \hspace{1cm} (M_j=M_k)
  - $M_j$ is a subset of $M_k$ \hspace{1cm} (M_j\subset M_k)
  - $M_k$ is a subset of $M_j$ \hspace{1cm} (M_j\supset M_k)
  - $M_j$ and $M_k$ do not overlap. \hspace{1cm} (M_j\cap M_k=\emptyset)

Every time a machine is freed, the job is selected that can be processed on the smallest number of machines.

- Least Flexible Job first (LFJ) rule
- LFJ is optimal for $P_2 | p_j = 1, M_j | C_{\text{max}}$ and for $P_m | p_j = 1, M_j | C_{\text{max}}$ when the $M_j$ sets are nested (pairwise exchange).
Consider $P_4 | p_j = 1, M_j | C_{\text{max}}$ with eight jobs. The eight $M_j$ sets are:

- $M_1 = \{1, 2\}$
- $M_2 = M_3 = \{1, 3, 4\}$
- $M_4 = \{2\}$
- $M_5 = M_6 = M_7 = M_8 = \{3, 4\}$

LFM (Least Flexible Machine) and LFM-LFJ do not guarantee optimality for this example either.
Makespan with Preemptions (1)

Linear programming formulation for \( P_{m} \mid prmp \mid C_{max} \)

The variable \( x_{ij} \) represents the total time job \( j \) spends on machine \( i \).

\[
\text{Minimize } C_{max} \text{ subject to }
\]

\[
\sum_{i=1}^{m} x_{ij} = p_j
\]

\[
\sum_{i=1}^{m} x_{ij} \leq C_{max}
\]

\[
\sum_{j=1}^{n} x_{ij} \leq C_{max}
\]

\[
x_{ij} > 0
\]

processing time of job \( j \)

processing on each machine is less than makespan

processing time of each job is less than makespan

positive execution fragments
The solution of a linear program yields the processing of each job on each machine.

A schedule must be generated in addition.

Lower bound: \( C_{\text{max}} \geq \max \left\{ p_1, \sum_{j=1}^{n} p_j / m \right\} = C_{\text{max}}^* \)

Algorithm Minimizing Makespan with Preemptions

1. Nondelay processing of all jobs on a single machine without preemption \( \Rightarrow \) makespan \( \leq m \cdot C_{\text{max}}^* \)
2. Cutting of this schedule into \( m \) parts
3. Execution of each part on a different machine
LRPT Rule

Longest Remaining Processing Time first (LRPT)

- Preemptive version of Longest Processing Time first (LPT)
- This method may generate an infinite number of preemptions.

Example: 2 jobs with $p_1 = p_2 = 1$ and 1 machine

The algorithm uses the time period $\varepsilon$.
- Time $\varepsilon$ after the previous decision the situation is evaluated again.

The makespan of the schedule is 2 while the total completion time is $4 - \varepsilon$.
- The optimal (non preemptive) total completion time is 3.

The following proofs are based on a discrete time framework.
- Machines are only preempted at integer times.
Vector Majorization

Vector of remaining processing times at time $t$

$$(p_1(t), p_2(t), \ldots, p_n(t)) = \bar{p}(t).$$

A vector $\bar{p}(t)$ majorizes a vector $\bar{q}(t)$, $\bar{p}(t) \geq_m \bar{q}(t)$, if

$$\sum_{j=1}^{k} p_{(j)}(t) \geq \sum_{j=1}^{k} q_{(j)}(t)$$

holds for all $k = 1, \ldots, n$.

$p_{j}(t)$ is the $j^{th}$ largest element of $\bar{p}(t)$.

Example

Consider the two vectors $\bar{p}(t) = (4, 8, 2, 4)$ and $\bar{q}(t) = (3, 0, 6, 6)$.

Rearranging the elements within each vector and putting these in decreasing order results in vectors $(8, 4, 4, 2)$ and $(6, 6, 3, 0)$.

It can be easily verified that $\bar{p}(t) \geq_m \bar{q}(t)$. 
If \( \bar{p}(t) \geq_m \bar{q}(t) \) then LRPT applied to \( \bar{p}(t) \) results in a larger or equal makespan than obtained by applying LRPT to \( \bar{q}(t) \).

Induction hypothesis: The lemma holds for all pairs of vectors with total remaining processing time less than or equal to \( \sum_{j=1}^{n} p_j(t) - 1 \) and \( \sum_{j=1}^{n} q_j(t) - 1 \), respectively.

Induction base: Vectors 1, 0, …, 0 and 1, 0, … 0.

After LRPT is applied for one time unit on \( p(t) \) and \( q(t) \), respectively, then we obtain at time \( t+1 \) the vectors \( p(t+1) \) and \( q(t+1) \) with

\[
\sum_{j=1}^{n} p_j(t+1) \leq \sum_{j=1}^{n} p_j(t) - 1 \quad \text{and} \quad \sum_{j=1}^{n} q_j(t+1) \leq \sum_{j=1}^{n} q_j(t) - 1 .
\]

If \( \bar{p}(t) \geq_m \bar{q}(t) \), then \( \bar{p}(t+1) \geq_m \bar{q}(t+1) \).
Result of the LRPT Rule

LPRT yields an optimal schedule for $P_m | prmp | C_{\text{max}}$ in discrete time.

We consider only problems with more than $m$ jobs remaining to be processed.

Induction hypothesis: The lemma holds for any vector $\overline{p}(t)$ with

$$\sum_{j=1}^{n} p_j(t) \leq N - 1.$$  

We consider a vector $\overline{p}(t)$ with

$$\sum_{j=1}^{n} p_j(t) = N.$$  

If LRPT is not optimal for $\overline{p}(t)$, then another rule $R$ must be optimal.

$R$ produces vector $\overline{q}(t+1)$ with

$$\overline{q}(t+1) \geq_m \overline{p}(t+1).$$

From time $t+1$ on, $R$ uses LRPT as well due to our induction hypothesis.

Due to the LRPT property, $R$ cannot produce a smaller makespan than LRPT.
LRPT in Discrete Time

Consider two machines and three jobs 1, 2 and 3, with processing times 8, 7, and 6.

\[ C_{\text{max}}(\text{LRPT}) = C_{\text{max}}(\text{OPT}) = 11. \]

Remember: Ties are broken arbitrarily!
LRPT in Continuous Time

Consider the same jobs as in the previous example. As preemptions may be done at any point in time, processor sharing takes place. $C_{\text{max}}(LRPT) = C_{\text{max}}(\text{OPT}) = 10.5$.

To prove that LRPT is optimal in continuous time, multiply all processing times by a very large integer $K$ and let $K$ go to $\infty$. 

```
1
2
1, 2, 3
2, 3
1, 2, 3
```
Lower Bound for Uniform Machines

\[ Q_m \mid prmp \mid C_{\text{max}} \]

\[ C_{\text{max}} \geq \max \left\{ \frac{p_1}{v_1}, \frac{p_1 + p_2}{v_1 + v_2}, \frac{\sum_{j=1}^{m-1} p_j}{\sum_{j=1}^{m-1} v_j}, \frac{\sum_{j=1}^{n} p_j}{\sum_{j=1}^{n} v_j} \right\} \]

for \( v_1 \geq v_2 \geq \ldots \geq v_m \)

Comparison: \( P_m \mid prmp \mid C_{\text{max}} \)

\[ C_{\text{max}} \geq \max \left\{ p_1, \frac{\sum_{j=1}^{n} p_j}{m} \right\} \]
Longest Remaining Processing Time on the Fastest Machine first (LRPT – FM) yields an optimal schedule with infinitely many preemptions for $Q_m \mid \text{prmp} \mid C_{\text{max}}$:

- At any point in time the job with the largest remaining processing time is assigned to the fastest machine.

Proof for a discrete framework with respect to speed and time

- Replace machine $j$ by $v_j$ machines of unit speed.
- A job can be processed on more than one machine in parallel, if the machines are derived from the same machine.

Continuous time:

- All processing times are multiplied by a large number $K$.
- The speeds of the machines are multiplied by a large number $V$.

The LRPT-FM rule also yields optimal schedules if applied to $Q_m \mid r_j, \text{prmp} \mid C_{\text{max}}$. 
Application of LRPT-FM

- 2 machines with speed $v_1 = 2$, $v_2 = 1$
- 3 jobs with processing times 8, 7, and 6
Different argument for SPT for total completion time without preemptions on a single machine

$p_{(j)}$: processing time of the job in position j on the machine

$$\sum C_j = n \cdot p_{(1)} + (n-1) \cdot p_{(2)} + \ldots + 2 \cdot p_{(n-1)} + p_{(n)}$$

$\Rightarrow p_{(1)} \leq p_{(2)} \leq p_{(3)} \leq \ldots \leq p_{(n-1)} \leq p_{(n)}$ must hold for an optimal schedule.
\( \sum C_j \) without Preemptions (2)

SPT rule is optimal for \( P_m \| \sum C_j \)

- The proof is based on the same argument as for single machines.
- Jobs with processing time 0 are added until \( n \) is a multiple of \( m \).
  - The sum of the completion time has \( n \) additive terms with one coefficient each:
    - \( m \) coefficients with value \( n/m \)
    - \( m \) coefficients with value \( n/m - 1 \)
    - \( \vdots \)
    - \( m \) coefficients with value 1
- The SPT schedule is not the only optimal schedule.
\[ \sum w_j C_j \text{ without Preemptions} \]

<table>
<thead>
<tr>
<th>jobs</th>
<th>1</th>
<th>2</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>( p_j )</td>
<td>1</td>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>( w_j )</td>
<td>1</td>
<td>1</td>
<td>3</td>
</tr>
</tbody>
</table>

- 2 machines and 3 jobs
- With the given values any schedule is WSPT.
- If \( w_1 \) and \( w_2 \) are reduced by \( \varepsilon \)
  \( \Rightarrow \) WSPT is not necessarily optimal.

- Tight approximation factor

\[
\frac{\sum w_j C_j (\text{WSPT})}{\sum w_j C_j (\text{OPT})} \leq \frac{1}{2} (1 + \sqrt{2})
\]

- \( P_m \parallel \sum w_j C_j \) is NP hard.
$P_m \mid prec \mid \sum C_j$ is strongly NP-hard.

The CP rule is optimal for $P_m \mid p_j = 1, \text{outtree} \mid \sum C_j$.

- The rule is valid if at most $m$ jobs are schedulable.
- $t_1$ is the last time the CP rule is not applied but rule R.
  - String 1 is the longest string not assigned at $t_1$
  - String 2 is the shortest string assigned at $t_1$
  - $C_1'$ is the completion time of the last job of string 1 under R
  - $C_2'$ is the completion time of the last job of string 2 under R
- If $C_1' \geq C_2' + 1$ and machines are idle before $C_1' - 1$, then CP is better than R; otherwise CP is as good as R.

However, the CP rule is not always optimal for intrees.
Other $\sum C_j$ Problems

- The LFJ rule is optimal for $P_m|p_j=1,M_j|\sum C_j$ when the $M_j$ sets are nested.
- The $R_m||\sum C_j$ problem can be formulated as an integer program
  - Although linear integer programming is NP-hard this program has a special structure that allows a solution in polynomial time.
  - $x_{ikj}=1$ if job $j$ is scheduled as the $k^{th}$ to last job on machine $i$.
  - $x_{ikj}$ are 0-1 integer variables.

Minimize $\sum_{i=1}^{m} \sum_{j=1}^{n} \sum_{k=1}^{n} kp_{ij} x_{ikj}$ subject to

\[
\sum_{i=1}^{m} \sum_{k=1}^{n} x_{ikj} = 1 \quad j = 1,\ldots, n
\]

\[
\sum_{j=1}^{n} x_{ikj} \leq 1 \quad i = 1,\ldots, m \text{ and } k = 1,\ldots, n
\]

$x_{ikj} \in \{0,1\}$ \quad $i = 1,\ldots, m$, $k = 1,\ldots, n$, and $j = 1,\ldots, n$
Example $R_m \| \sum C_j$

- 2 machines and 3 jobs
- The optimal solution corresponds to $x_{121} = x_{112} = x_{213} = 1$. All other $x_{ikj}$ are 0. The optimal schedule is not nondelay.

Machine 1

Machine 2

0 4 8
The nonpreemptive SPT rule is also optimal for $P_m|prmp|\sum C_j$.

$Q_m|prmp|\sum C_j$ can be solved by the **Shortest Remaining Processing Time on the Fastest Machine (SRPT-FM)** rule.

- Useful lemma: There is an optimal schedule with $C_j \leq C_k$ when $p_j \leq p_k$ for all $j$ and $k$. (Proof by pairwise exchange)
- Under SRPT-FM, we have $C_n \leq C_{n-1} \leq \ldots \leq C_1$.
- Assumption: There are $n$ machines.
  - If there are more jobs than machines, then machines with speed 0 are added.
  - If there are more machines than jobs, then the slowest machines are not used.
\[ \sum C_j \text{ with Preemptions (2)} \]

\[
\begin{align*}
  v_1 C_n &= p_n \\
  v_2 C_n + v_1 (C_{n-1} - C_n) &= p_{n-1} \\
  v_3 C_n + v_2 (C_{n-1} - C_n) + v_1 (C_{n-2} - C_{n-1}) &= p_{n-2} \\
  & \vdots \\
  v_n C_n + v_{n-1} (C_{n-1} - C_n) + v_1 (C_1 - C_2) &= p_1
\end{align*}
\]

Adding these equations yields

\[
\begin{align*}
  v_1 C_n &= p_n \\
  v_2 C_n + v_1 C_{n-1} &= p_n + p_{n-1} \\
  v_3 C_n + v_2 C_{n-1} + v_1 C_{n-2} &= p_n + p_{n-1} + p_{n-2} \\
  & \vdots \\
  v_n C_n + v_{n-1} C_{n-1} + \ldots + v_1 C_1 &= p_n + p_{n-1} + \ldots + p_1
\end{align*}
\]
Let $S'$ be an optimal schedule with $C'_n \leq C'_{n-1} \leq \ldots \leq C'_1$ (see the lemma). Then we have $C'_n \geq p_n/v_1 \Rightarrow v_1C'_n \geq p_n$.

The amount of processing on jobs $n$ and $n-1$ is upper bounded by

\[ \leq (v_1 + v_2)C'_n + v_1(C'_{n-1} - C'_n). \Rightarrow v_2C'_n + v_1C'_{n-1} \geq p_n + p_{n-1} \]

Similarly, we obtain

\[ v_kC'_n + v_{k-1}C'_{n-1} + \ldots + v_1C'_{n-k+1} \geq p_n + p_{n-1} + \ldots + p_{n-k+1} \]

This yields

\[ v_1C'_n \geq v_1C_n \]

\[ v_2C'_n + v_1C'_{n-1} \geq v_2C_n + v_1C_{n-1} \]

\[ \vdots \]

\[ v_nC'_n + v_{n-1}C'_{n-1} + \ldots + v_1C'_1 \geq v_nC_n + v_{n-1}C_{n-1} + \ldots + v_1C_1 \]
We want to transform this system of inequalities into a new system such that

- inequality \( i \) is multiplied by \( \alpha_i \geq 0 \) and
- the sum of all those transformed inequalities yields \( \sum C'_j \geq \sum C_j \).
- The proof is complete, if those \( \alpha_i \) exists.
- \( \alpha_i \) must satisfy

\[
\begin{align*}
v_1\alpha_1 + v_2\alpha_2 + \ldots + v_n\alpha_n &= 1 \\
v_1\alpha_2 + v_2\alpha_3 + \ldots + v_{n-1}\alpha_n &= 1 \\
&\vdots \\
v_1\alpha_n &= 1
\end{align*}
\]

Those \( \alpha_i \) exists as \( v_1 \geq v_2 \geq \ldots \geq v_n \) holds.

SRPT-FM produces an optimal schedule with $\sum C_j = 116$
Due – Date Related Objectives

\[ P_m \parallel C_{\text{max}} \propto P_m \parallel L_{\text{max}} \text{ (all due dates 0)} \]

\[ \Rightarrow \text{The problem is NP-hard.} \]

\[ Q_m | prmp | L_{\text{max}} \]

Assume \( L_{\text{max}} = z \)

\[ \Rightarrow C_j \leq d_j + z \]

\[ \Rightarrow \text{set } d_j = d_j + z \text{ (hard deadline)} \]

\[ \Rightarrow \text{Hard deadlines are release dates in the reversed problem.} \]

\[ \Rightarrow \text{Finding a schedule for this problem is equivalent to solving } \]

\[ Q_m | r_j, prmp | C_{\text{max}} \]

\[ \Rightarrow \text{If all jobs in the reverse problem “finish” at a time not smaller than 0, then there exists a schedule for } Q_m \mid prmp \mid L_{\text{max}} \text{ with } L_{\text{max}} \leq z. \]

\[ \Rightarrow \text{The minimum value for } z \text{ can be found by a simple search.} \]
Example P2 | prmp | $L_{\text{max}}$

<table>
<thead>
<tr>
<th>jobs</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
</tr>
</thead>
<tbody>
<tr>
<td>$d_j$</td>
<td>4</td>

Is there a feasible schedule with $C_{\text{max}} \leq 9$?
Flow Shops

- Each job must follow the same route.
  - There is a sequence of machines.

- There may be limited buffer space between neighboring machines.
  - The job must sometimes remain in the previous machine: Blocking.

- The main objective in flow shop scheduling is the makespan.
  - It is related to utilization of the machines.

- If the First-come-first-served principle is in effect, then jobs cannot pass each other.
  - Permutation flow shop
Unlimited Intermediate Storage

- Permutation Schedule: $j_1, j_2, \ldots, j_n$

  $C_{i,j_i} = \sum_{l=1}^{i} p_{l,j_i}$ \quad $i = 1, \ldots, m$

  $C_{1,j_k} = \sum_{l=1}^{k} p_{1,j_l}$ \quad $k = 1, \ldots, n$

  $C_{i,j_k} = \max(C_{i-1,j_k}, C_{i,j_{k-1}}) + p_{i,j_k}$

  \[ i = 2, \ldots, m \quad k = 2, \ldots, n \]

- There is always an optimal schedule without job sequence changes in the first two and last two machines.

  $\Rightarrow$ F2$|| C_{\text{max}}$ and F3$|| C_{\text{max}}$ do not require a job sequence change in some optimal schedule.
Directed Graph for $F_{m|prmu|C_{\text{max}}}$
Example F4|prmu|C_{max}

5 jobs on 4 machines with the following processing times

Directed Graph in the Example

Critical path
Gantt Chart in the Example
Two $m$ machine permutation flow shops with $n$ jobs are considered with $p_{ij}(1) = p_{m+1-i,j}^{(2)}$.

- $p_{ij}(1)$ and $p_{ij}(2)$ denote the processing times of job $j$ in the first and the second flow shop, respectively.

Sequencing the jobs according to permutation $j_1, \ldots, j_n$ in the first flow shop produces the same makespan as permutation $j_n, \ldots, j_1$ in the second flow shop.

- The makespan does not change if the jobs traverse the flow shop in the opposite direction in reverse order (Reversibility).
5 jobs on 4 machines with the following processing times (original processing times in parentheses)

<table>
<thead>
<tr>
<th>jobs</th>
<th>$j_1$</th>

Example Reversibility (2)

Original problem

Reverse problem
Example Reversibility (3)
F2||C_{max} with unlimited storage in between the two machines

The optimal solution is always a permutation.

- Johnson’s rule produces an optimal schedule.
  - The job set is partitioned into 2 sets.
    - Set I: all jobs with \( p_{1j} \leq p_{2j} \)
    - Set II: all jobs with \( p_{2j} < p_{1j} \)
  - SPT (1) – LPT(2) schedule:
    - All jobs of Set I are scheduled first in increasing order of \( p_{1j} \) (SPT).
    - All jobs of Set II are scheduled afterwards in decreasing order of \( p_{2j} \) (LPT).

- There are many other optimal schedules besides SPT(1) – LPT(2) schedules.
  - The SPT(1)-LPT(2) schedule structure cannot be generalized to yield optimal schedules for flow shops with more than two machines.
Proof of Johnson’s Rule (1)

Contradiction: Assume that another schedule S is optimal.

⇒ There is a pair of adjacent jobs $j$ followed by $k$ such that one of the following conditions hold:

- Job $j$ belongs to Set II and job $k$ to Set I; (Case 1)
- Jobs $j$ and $k$ belong to Set I and $p_{1j} > p_{1k}$; (Case 2)
- Jobs $j$ and $k$ belong to Set II and $p_{2j} < p_{2k}$; (Case 3)

- Sequence in schedule S: job $l \Rightarrow job j \Rightarrow job k \Rightarrow job h$

$C_{ij}$ : completion time of job $j$ on machine $i$ in schedule S

$C'_{ij}$ : completion time of job $j$ on machine $i$ in the new schedule.
Proof of Johnson’s Rule (2)

- Interchange of j and k
  - Starting time \((C_{1l} + p_{1j} + p_{1k})\) of job \(h\) on machine 1 is not affected.
  - Starting time of job \(h\) on machine 2:
    \[
    C_{2k} = \max \left( \max \left( C_{2l}, C_{1l} + p_{1j} \right) + p_{2j}, C_{1l} + p_{1j} + p_{1k} \right) + p_{2k}
    \]
    \[
    = \max \left( C_{2l} + p_{2j} + p_{2k}, C_{1l} + p_{1j} + p_{2j} + p_{2k}, C_{1l} + p_{1j} + p_{1k} + p_{2k} \right)
    \]
    \[
    C'_{2j} = \max \left( C_{2l} + p_{2k} + p_{2j}, C_{1l} + p_{1k} + p_{2k} + p_{2j}, C_{1l} + p_{1k} + p_{1j} + p_{2j} \right)
    \]

- Case 1: \(p_{1j} > p_{2j}\) and \(p_{1k} \leq p_{2k}\)
  - \(C_{1l} + p_{1k} + p_{2k} + p_{2j} < C_{1l} + p_{1j} + p_{1k} + p_{2k}\)
  - \(C_{1l} + p_{1k} + p_{1j} + p_{2j} \leq C_{1l} + p_{1j} + p_{2j} + p_{2k}\)
  - \(C'_{2j} \leq C_{2k}\)

- Case 2: \(p_{1j} \leq p_{2j}\), \(p_{1k} \leq p_{2k}\), and \(p_{1j} > p_{1k}\)
  - \(C_{1l} + p_{1k} + p_{2k} + p_{2j} \leq C_{1l} + p_{1j} + p_{2j} + p_{2k}\)
  - \(C_{1l} + p_{1k} + p_{1j} + p_{2j} \) (reversibility property)

- Case 3 is similar to Case 2 (reversibility property).
Formulation as a Mixed Integer Program (MIP)

- Decision variable $x_{jk} = 1$, if job $j$ is the $k^{th}$ job in the sequence.
- $I_{ik}$: amount of idle time on machine $i$ between the processing of jobs in position $k$ and $k+1$
- $W_{ik}$: amount of waiting time of job in position $k$ between machines $i$ and $i+1$
- $\Delta_{ik}$: difference between start time of the job in position $k+1$ on machine $i+1$ and completion time of the job in position $k$ on machine $i$
- $p_{i(k)}$: processing time of the job in position $k$ on machine $i$

\[ \Delta_{ik} = I_{ik} + p_{i(k+1)} + W_{i,k+1} = W_{ik} + p_{i+1(k)} + I_{i+1,k} \]
Graphical Description of $\Delta_{ik}$

$\Delta_{ik}$

$I_{ik}$

$W_{i,k+1}$

Machine $i$

$p_{i(k)}$

$p_{i(k+1)}$

Machine $i+1$

$p_{i+1(k-1)}$

$p_{i+1(k)}$

$p_{i+1(k+1)}$

$W_{ik} > 0$ and $l_{i+1, k} = 0$
MIP for $F_m \mid \text{prmu} \mid C_{\text{max}}$ (1)

- Minimizing the makespan $\equiv$ Minimizing the idle time on machine $m$

$$\sum_{i=1}^{m-1} p_{i(1)} + \sum_{j=1}^{n-1} I_{mj}$$

- Remember: $p_{i(k)} = \sum_{j=1}^{n} x_{jk} p_{ij}$

$\Rightarrow$ there is only one job at position $k$!
MIP for $F_m \mid \text{prmu} \mid C_{\text{max}}$ (2)

\[
\min \left( \sum_{i=1}^{m-1} \sum_{j=1}^{n} x_{ij} p_{ij} \right) + \sum_{j=1}^{n-1} l_{mj}
\]

subject to

\[
\sum_{j=1}^{n} x_{jk} = 1 \quad k = 1, \ldots, n
\]

\[
\sum_{k=1}^{n} x_{jk} = 1 \quad j = 1, \ldots, n
\]

\[
l_{ik} + \sum_{j=1}^{n} x_{j,k+1} p_{ij} + W_{i,k+1} - W_{ik} - \sum_{j=1}^{n} x_{jk} p_{i+1,j} - l_{i+1,k} = 0
\]

for $k = 1, \ldots, n-1; i = 1, \ldots, m-1$

\[
W_{i1} = 0 \quad i = 1, \ldots, m-1
\]

\[
x_{jk} \in \{0,1\} \quad j=1, \ldots, n
\]

\[
l_{1k} = 0 \quad k = 1, \ldots, n-1
\]

\[
W_{ik} \geq 0 \quad i = 1, \ldots, m-1; k = 1, \ldots, n
\]

\[
l_{ik} \geq 0 \quad i = 1, \ldots, m; k = 1, \ldots, n-1
\]
F3∥C_{max}

- F3 || C_{max} is strongly NP-hard.
  - Proof by reduction from 3 – Partition

- An optimal solution for F3 || C_{max} does not require sequence changes.
  - F_m | prmu | C_{max} is strongly NP – hard.

- F_m | prmu, p_{ij} = p_j | C_{max} : proportionate permutation flow shop
  - The processing of job j is the same on each machine.

- C_{max} = \sum_{j=1}^{n} p_j + (m - 1) \max(p_1, ..., p_n) for

F_m | prmu, p_{ij} = p_j | C_{max} (independent of the sequence)
This is also true for F_m | p_{rj} = p_j | C_{max}.
Proportionate Flow Shop

Similarities between the single machine and the proportionate (permutation) flow shop environments

1. SPT is optimal for $1 \parallel \sum C_j$ and $F_m \mid \text{prmu}, p_{ij} = p_j \mid \sum C_j$.

2. The algorithms that produces and optimal schedule for $1 \parallel \sum U_j$ also results in an optimal schedule for $F_m \mid \text{prmu}, p_{ij} = p_j \mid \sum U_j$.

3. The algorithms that produces and optimal schedule for $1 \parallel h_{\text{max}}$ also results in an optimal schedule for $F_m \mid \text{prmu}, p_{ij} = p_j \mid h_{\text{max}}$.

4. The pseudo-polynomial dynamic programming algorithm $1 \parallel \sum T_j$ is also applicable to $F_m \mid \text{prmu}, p_{ij} = p_j \mid \sum T_j$.

5. The elimination criteria that hold for $1 \parallel \sum w_j T$ also hold for $F_m \mid \text{prmu}, p_{ij} = p_j \mid \sum w_j T_j$. 
Slope Heuristic

- Slope index $A_j$ for job $j$
  
  $A_j = -\sum_{i=1}^{m} (m - (2i - 1))p_{ij}$

- Sequencing of jobs in decreasing order of the slope index

- Consider 5 jobs on 4 machines with the following processing times

<table>
<thead>
<tr>
<th>jobs</th>
<th>$j_1$</th>
<th>$j_2$</th>
<th>$j_3$</th>
<th>$j_4$</th>
<th>$j_5$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$p_{1,jk}$</td>
<td>5</td>
<td>2</td>
<td>3</td>
<td>6</td>
<td>3</td>
</tr>
<tr>
<td>$p_{2,jk}$</td>
<td>1</td>
<td>4</td>
<td>3</td>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>$p_{3,jk}$</td>
<td>4</td>
<td>4</td>
<td>2</td>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>$p_{4,jk}$</td>
<td>3</td>
<td>6</td>
<td>3</td>
<td>5</td>
<td>5</td>
</tr>
</tbody>
</table>

Sequences 2,5,3,1,4 and 5,2,3,1,4 are optimal and the makespan is 32.

$A_1 = -(3 \times 5) - (1 \times 4) + (1 \times 4) + (3 \times 3) = -6$

$A_2 = -(3 \times 5) - (1 \times 4) + (1 \times 4) + (3 \times 6) = +3$

$A_3 = -(3 \times 3) - (1 \times 2) + (1 \times 3) + (3 \times 3) = +1$

$A_4 = -(3 \times 6) - (1 \times 4) + (1 \times 4) + (3 \times 2) = -12$

$A_5 = -(3 \times 3) - (1 \times 4) + (1 \times 1) + (3 \times 5) = +3$
